

A Framework for Connecting Natural Language and Symbol Sense in Mathematical Word Problems for English Language Learners

Rachael H. Kenney
Purdue University

Luciana C. de Oliveira University of Miami

Abstract

Working fluently within the multiple semiotic systems of the language of mathematics requires developing strong symbol sense and connecting meaning of symbols to meanings in natural language. Challenges can exist for English language learners (ELLs) when connecting natural language and symbolic representations, particularly in the context of a mathematical word problem. This article presents a framework that connects mathematical word problem solving stages to multiple semiotic systems while providing elements of symbol sense that ELLs can develop in order to work with mathematical word problems.

Discussion And Reflection Enhancement (DARE) Pre-Reading Questions

- 1. What challenges does mathematics language present to ELLs?
- 2. How is language used differently in mathematics than in other content areas?
- 3. What resources do ELLs bring to the classroom that can aid in their learning of mathematics?

Rachael H. Kenney (<u>rhkenney@purdue.edu</u>) is an Associate Professor at Purdue University with a joint appointment in the Department of Mathematics and Department of Curriculum and Instruction. Dr. Kenney's research focuses on issues related to students' interactions and reflections on symbols and representation in mathematics.

Luciana C. de Oliveira (<u>ludeoliveira@yahoo.com</u>) is Associate Professor in the Department of Teaching and Learning at the University of Miami. Dr. de Oliveira's research focuses on issues related to teaching K-12 English language learners (ELLs) and teacher preparation for ELLs.

A Framework for Connecting Natural Language and Symbol Sense in Mathematical Word Problems for English Language Learners

Challenges in Mathematics for ELLs: The Case of Word Problems

An examination of ELL and non-ELL performance in mathematics shows small gaps for strictly computational problems, but large gaps on word problems and problems that contain linguistically complex terms (Abedi, 2004). An interplay between symbolic and natural language is clearly present when solving mathematical word problems where students must be able to decode not only the language of the question and the overlaying context, but must also have knowledge of and be able to represent words with the This problem contains common keywords that might allow

Mathematics can be considered a language in itself, com- question. It is clear that many students (both ELLs and non-

between multiple semiotic systems such as natural and ties for ELLs on word problems include: a lack of built-in symbolic languages requires developing strong symbol contextual clues found in literary narratives (Carey, Fennesense, which includes having an awareness that one can ma, Carpenter, & Franks, 1995), unfamiliar cultural consuccessfully create symbolic relationships which represent texts and interpretations (Solano-Flores & Trumbull, 2003), written information; experiencing different roles played by reading comprehension issues (Schleppegrell, 2007), the symbols; and appreciating the power of symbols to display artificial contexts of word problems (Wiest, 2001), and othand explain relationships expressed in natural language er issues (Celedón-Pattichis, 2003). Many suggestions have been offered for helping ELLs work with word problems, including helping students recognize and understand key-Research and personal experiences tell us that the complex- words (e.g., more than, take away, of, per, total, etc.), modity of working in multiple semiotic systems in mathematics ifying the language complexity of the problem, and using presents challenges for all learners. > These useful suggestions for helping ELLs may be easier to implement in some problems than in others. Consider, for example, the first part of a constructed response word problem selected from 6th grade sample items provided by the Indiana Statewide Testing for Educational Progress (ISTEP+) Grades 6 through 8 (Indiana Department of Education, 2012):

> > Sue bought 4 rings for her mom. Each ring cost the same amount of money. The total cost was \$31. What is the cost per ring?

mathematical symbols needed to effectively answer the an ELL to recognize that the cost per ring is the total cost

lution of the problem. We need recognize only that we have ent ways at different stages of problem solving. four things that each cost the same and we spent \$31 in total.

Now consider another problem from the same set of sample items (Figure 1) (Indiana Department of Education, 2012). Natural language use in mathematics is characterized by problem on their own, thinking carefully about the understanding of both the natural and symbolic languages needed to solve it.

Grade 7 Constructed Response Item (Alg. & Functions/Problem Solving)

Irene spent half of her weekly allowance playing miniature golf. To earn more money, her parents let her wash the car for \$4.

Write an equation that can be used to determine Irene's weekly allowance (a) if she has \$12 left after washing the car.

Figure 1. ISTEP+ Mathematics Sample Grade 7 Item

A Framework for Looking at Word Problems

We know that when working with mathematical word problems, ELLs need to access the language of mathematfunctions: (a) natural language introduces, contextualizes, and describes a mathematical problem; (b) symbolism is used for finding the solution of the problem; and (c) visual images deal with visualizing the problem graphically or 2004, 2005). All of these systems may involve vocabulary. sentence structures, contexts, and representations that are examine difficulties with connecting natural language and symbolic representations in word problems. We also know that in most mathematical problem solving situations we can break the solving procedure down into different *stages* which may include: formulating the problem from a realworld application, solving the problem using some form of when transitioning from words to symbols. mathematical representation (symbolic, graphical, etc.), and interpreting and checking the solution in the context of the

divided by the number of rings. The language is relatively real-world situation. When working on a mathematical simple, and knowing what "rings" are is not key to the so-problem, learners call upon the semiotic systems in differ-

Multiple Semiotic Systems: Natural Language and Symbolism

An examination of this problem shows that although some the dominance of relational processes presented through common keywords like "more" and "left" are found in the verbs that show relationships, such as be, have, and repretext, they are not as easily transferrable to mathematical sent, and the frequent use of nominalizations, the expressymbols as they might be in the first example. We suggest sion as a noun or nominal group of what would in everyday that a problem like this requires a deeper understanding of language be a verb, adjective, or conjunction (e.g., multiplihow the larger sentence structure connects to mathematical cation, exponent). For example, in the following grade 6 symbols. We will revisit this problem in more detail below ISTEP+ test item, "What is the area, in square feet, of a to look carefully at potential ways in which ELLs may circle with a diameter of 8 feet? Use 3.14 for pi," the relastruggle or succeed in working with it. We recommend that tional process is used in the question along with the nomireaders take a moment before continuing and solve this nalization the area of a circle with a diameter of 8 feet. (Indiana Department of Education, 2012).

> Mathematical content is presented using natural language to carry forward the argument (O'Halloran, 2000). Making sense of the natural language in a word problem is something with which ELLs have commonly been seen to struggle (de Oliveira & Cheng, 2011; Martiniello, 2008).

Symbolism is used in mathematics for the solution process (O'Halloran, 2000). This semiotic system is often a cause of great confusion for all students due, in part, to the multiple ways in which symbols are used. For example, symbols name, label, signify, communicate, simplify, represent, reveal structure, and display relationships (Arcavi, 1994; Kinzel, 1999; Pimm, 1995; Stacey & MacGregor, 1999). For example, when stating the often used Pythagorean Theorem, instead of continually making the cumbersome statement "the square of the hypotenuse of a right triangle is equal to the sum of the squares of the two adjacent sides," we label the sides of the triangle as a, b, and c (see Figure 2) and simply state $c^2 = a^2 + b^2$. Here symbols make it much easier to quickly communicate and display the geometric relationship. Symbols also play multiple roles within a single mathematical statement, acting as generalized numbers, ics through multiple semiotic systems that fulfill different arguments of a function, parameters, unknown numbers. and variables (Usiskin, 1988). For example, in the symbolic representation for an equation of a circle, $x^2+y^2=r^2$, r represents the radius of the circle and is a constant or parameter for the equation, while x and y are variables. In the diagrammatically (de Oliveira & Cheng, 2011; O'Halloran equation 50 = 5x, we can think of x as an unknown number rather than a variable because it can have only one value here. These numerous roles played by symbols make matnew or unfamiliar to ELLs (Martiniello, 2008); we have ters even more complicated as ELLs try to make connecchosen to focus primarily on the first two in this paper to tions between the language used to describe a mathematical problem and the symbols required to solve the problem. These symbols may exist across many different languages and understanding them is challenging regardless of one's native language, but ELLs need to draw on knowledge of a language they are still developing in order to use symbols

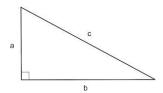

Figure 2. Using Symbols As Labels on a Triangle For the Pythagorean Theorem.

When working with mathematical word problems, the interaction with natural language occurs typically in the formulation and interpreting/checking stages of problem solving while the solving stage is heavily dependent on an interaction with and manipulation of symbols (including numbers and/or letters) or analysis of visual representa- In this section, we use a standardized test item from the tions. Thus, the symbolic language and visual image systems (and the links between them) play a primary role in tion, 2012) to identify the potential challenges for ELLs. In this stage.

A Focus on Symbol Sense

Within the natural language and symbolic semiotic systems, we can identify one common important element that we choose to focus on in this paper: symbol sense, which

Arcavi (1994) describes as "a quick or accurate appreciation, understanding, or instinct regarding symbols" (p. 31) that is involved at all stages of mathematical problem solving. Kenney (2008) has used a symbol sense framework (constructed using adaptations of work by Pierce and Stacey (2001, 2002) and Arcavi (1994, 2005)), to investigate students' reasoning with mathematical symbols at different problem solving stages. In this paper, we have modified this framework to connect the problem solving stages to the semiotic systems and highlight the elements of symbol sense that ELLs may need to work with mathematical word problems (Table 1).

Applying Framework to a Standardized Test Item

ISTEP+ Grades 6 through 8 (Indiana Department of Educathe current era of teacher accountability, we know from experience that teachers are drawing heavily on sample items and practice tests from the end-of-year exams that their students will take to help prepare students for these tests. The problem we have chosen to discuss here (see Figure 1) was purposefully selected from a sample test bank

A Framework for Symbol Sense for English Language Learners (ELLs)

Problem Solving Stage	Semiotic Systems	Examples of Symbol Sense Required
Formulation	Making sense of the natural language; Linking the natural language and symbolic systems	Knowing how and when to use symbols
		Knowing that symbols play different roles in different contexts
		Ability to select possible symbolic representations
		Knowing that chosen representation can be abandoned when they are not working
Solving	Working within the symbolism system	Recognizing conventions and basic properties Knowing meaning of symbols
		Knowing order of operations
		Knowing properties of operations
	Linking the symbolism and visual image systems	Knowing when to abandon symbols for other visual approaches
		Knowing meaning of symbols in a visual representation (e.g. labels)
		Linking key features
Interpretation and Checking	Linking back to the natural lan- guage system; Making meaningful sense of how	Linking symbol meanings to personal expectations Linking symbol meanings to the problem
	the result connects to the original question	Using symbols to communicate results

The task to as explained in de Oliveira (2012), makes them more likely complete is given in the clause Write an equation that can to pose challenges for ELLs. We, therefore, explain some be used to determine Irene's weekly allowance (a) if she challenges that ELLs face in particular.

Analysis of Part 1 of the Task

An analysis of the word problem in Figure 1 shows that natural language and symbols are interconnected in students' possible solutions. This test item has two sets of tasks that students are to complete, one starting with Irene spent half... (we will refer to this as Part 1) and the other starting with *This week Irene used....* (Part 2). In Table 2, we break down Part 1 and connect the framework for symbol sense to a linguistic analysis of the different clauses in the task.

Part 1 begins by introducing a context for the situation. The concept of weekly allowance is introduced in the first clause, which may cause difficulties for ELLs who may not be familiar with this concept and may not recognize it as an amount of money. In the same clause, we also see the word

because it represents a similar linguistic structure as text- half which students have to connect to the symbolic reprehas \$12 left after washing the car. This clause gives a command with the verb write and what it is that students are supposed to write, an equation. Further information is provided about an equation with an embedded clause that can be used to determine Irene's weekly allowance (a) if she has \$12 left after washing the car. We notice here that the variable is provided through the symbol (a) referring to Irene's weekly allowance, which could present an additional challenge for ELLs. This symbol has to be used in the construction of the equation, as this test may be completed on a computer that would not recognize if another symbol, such as (x), were used instead. The conditional clause if she has \$12 left after washing the car is another important piece of information for students to consider. If clauses are very common in mathematics and have been found to cause particular difficulties for ELLs (Fernandes, Anhalt, & Civil, 2009; Martiniello, 2008). Making sense of the phrase \$12 left includes understanding that the word left means

Table 2 Application of Framework and Linguistic Analysis of Part 1 of the I-STEP Problem

Clause in Problem	Problem Solving Stage	Symbols Involved	Linguistic Analysis: What is required linguistically to work with the problem?
Irene spent half of her weekly allowance playing miniature golf	Formulation	1/2	Linking the natural language expressed in the word <i>half</i> to the numeric representation ½ Making sense of the concept of <i>weekly allowance</i> being an amount of money
To earn more money, her parents let her wash the car for \$4.	Formulation	+4	Making sense of the concept of earning as meaning to receive more Linking receiving more to addition operation Making meaning by inferring that she will only wash the car once
Write an equation to determine Irene's weekly allowance, a, if she has \$12 left after washing the car.	Formulation Interpretation	$a - \frac{1}{2}a + 4 = 12$ or $\frac{1}{2}a + 4 = 12$ $a = 2(12 - 4)$	Making sense of keywords in the phrase \$12 left as indicating that this amount is what remains from allowance after washing the car Recognizing that she earned the extra 4 dollars after she had spent half (it was not $\frac{1}{2}(a+4)$). Interpreting the produced equation with the natural language to check the meaning of what they produced

she interprets (1/2)a as already representing what is *left*.

However, de-from the natural language system to the symbolism system. termining the right-hand side of this equation involves a Some interpretation should also be used to check the meanpotentially complex interaction with the problem's natural ing of the produced equation against the original natural language to mentally undo the actions on a, which adds to language. The symbol sense for selecting appropriate symthe complexity of a problem like this. That is, to come up bols to use is done, in part, for the learner by telling them with the equation a = 2(12 - 4), the learner would need to to use (a) for allowance. However, to set up the equation, work with the values in a different way than how they are students must fit this symbol into the larger symbolic reprepresented in the problem. In this instance, it may be easier sentation. It is possible that students could determine the to think of a as part of what is being manipulated in the value of the allowance by doing mental computations, but

remaining and understanding that the equation does not equation and not the result. This allows for a more direct necessarily require a subtraction. For example, a student translation from the natural language to the symbolic form, could write the equation (1/2)a + 4 = 12 directly if he or which lessens the challenges inherent in this translation process for ELLs.

Students may start to symbolize this problem by writing "a We see in Table 2 that Part 1 asks students to engage most-

Table 3 Application of Framework and Linguistic Analysis of Part 2 of the I-STEP Problem

Clause in Problem	Problem Solving Stage	Symbols Involved	Linguistic Analysis in relation to symbols sense: What is required to work with the problem?
This week Irene used her allowance to buy each of her 5 friends a bracelet	Formulation	5 friends 1 bracelet per friend	 Making meaning of the thing that is being bought versus the recipient of the action (Reading directly it looks like we could be buying friends instead of bracelets) Linking the natural language expressed through the word <i>each</i> with the number 1
and still had \$3 remaining.	Formulation	\$3	 Linking the word remaining to an idea that 3 dollars is what is left after spending (i.e., the result of buying bracelets).
Each bracelet cost the same amount of money.	Formulation	Could let <i>b</i> = cost of one bracelet	Linking the word each to understand that we can select one variable to represent any one of the bracelets
What was the cost of 1 bracelet?	Solving	1 st solve $\frac{1}{2}a + 4 = 12$ from Part 1	Linking the word <i>cost</i> to the expectation that the result will be an amount of money
	Formulation Solving Interpretation/Checking	Create equation:	Recognizing an action that is not explicitly stated in the problem
		16 - 5b = 3 Solve: $b = 13/5 = 2.6$	 Knowing that to find the cost of one bracelet, we have to find the total cost of all five bracelets and then di- vide.
			 Understanding that finding weekly allowance is not what the question is asking – need also to find a new amount of money, the cost of one bracelet by subtract- ing the cost of all bracelets from the total allowance and knowing that there will be \$3 left over
			Interpreting the equation against the natural language to check the meaning of equation
			• Interpreting the result 2.6 as \$2.60 to connect to the context in the natural language

be able to symbolize an equation using the letter a, so stu- er, being able to understand how different semiotic systems dents must draw on multiple symbol sense elements to are used in the construction of a word problem and how to complete the task.

Analysis of Part 2 of the Task

In Table 3, we continue with a breakdown of Part 2 of this task. Part 2 begins by identifying the time of the next situation- This week. In the clause, This week Irene used her allowance to buy each of her 5 friends a bracelet we see how Irene used her allowance, but the construction in this clause may cause difficulties for ELLs because each of her friends is put before a bracelet. The next sentence, Each bracelet cost the same amount of money establishes an important piece of information for students to solve the problem. ELLs have to connect the word *each* with the numerical representation 1, and recognize that the same variable or letter can represent every bracelet. The question What was the cost of 1 bracelet? shows what students need to be able to calculate.

In Part 2, students are required to go through multiple problem solving stages, though not all are explicit in the problem itself. This may cause additional difficulties for ELLs. They must first determine, using their equation from the first part, the actual value of a typical week's (and therefore "this week's") allowance. This involves proceeding through the solving stage. Here students must know the order and properties of operations for "undoing" the equation to get a by itself. Once the value of a is identified to be \$16, however, students must know that the letter a is no made back to natural language if the students try to interpret or check their solution.

Once they have found a, students need to be able to find the cost of one bracelet. The directions to show all work require the use of symbolization or visual images (i.e., mental computation will not suffice), so students must again engage in the formulation stage. Students may or may not choose to select a symbolic representation for the cost of a bracelet, such as c or b. Unlike the first part, they are not given directions on how to symbolize here. The symbolic representation b = (16 - 3)/5 can be used to find the solution, so only numbers are involved in the calculation. However, difficulties could arise, especially for ELLs, because the order in which the calculations need to occur is not the same order in which these values appear in the problem. This could potentially be problematic for ELLs. as they would have to figure out the order of the values by understanding the language that is expressing these values.

Implications for Classroom Teachers and Mathematics Teacher Educators

Teachers and teacher educators know well that the complexity of mathematics language presents challenges for all of the tools and resources that work well for them as they

this problem is structured in a way that it requires them to learners, and not just ELLs. As the example shows, howevtransition among these systems in solving a problem may present additional challenges for ELLs that are important for teachers to understand. There are additional linguistic demands for ELLs that make developing symbol sense and transitioning between the symbolic and natural language more of a challenge, as they learn to filter their existing and developing knowledge of mathematical language through a second natural language (Brown, 2005).

> In particular, the symbolic system may cause great confusion for ELLs because of the ways in which it needs to interact directly with the natural language system throughout the problem solving process. Teachers need to be aware of these potential difficulties and provide opportunities for ELLs to engage with natural language and symbols and the links between them in the context of mathematics teaching. In other words, symbol sense cannot be fully developed in absence of natural language; thus, it is not sufficient to allow ELLs to avoid language issues by engaging them in mainly symbolic tasks. If we expect students to know how these semiotic systems interact in the construction of mathematics, they need experiences that help them build understandings of the multiple semiotic systems at work in mathematics word problems.

A major part of meaning making in mathematics word problems is in the connections between natural language and symbolic representations. As Tables 2 and 3 indicate, the formulation and interpretation stages, where these connections are key, do not just appear once at the beginning longer necessary in their work. They need to know the or end of the problem but repeatedly throughout the whole meaning of this variable a as representing an unknown that, process. This suggests that teachers need to be aware of the once determined, will not change again. Links may also be additional challenges that ELLs developing their language proficiency may have throughout the entire problem. It is not just a matter of helping them remove words and create an equation – they need to develop meaning by constantly checking their symbol sense against the meanings in the natural language of the problem.

> As teachers, we need to build a better awareness of the additional challenges that ELLs face with word problems and identify ways to help them use the understandings of language and mathematics that they bring to the table to overcome these challenges. It is critical for teachers to make use of ELLs' many existing skills, ideas and strategies. For example, all students bring with them language and cultural resources (Celedón-Pattichis & Ramirez, 2012) which mathematics teachers should use in authentic ways when constructing word problems to motivate interest and build relationships with and among students. Teachers must also be careful not to relate language fluency with academic competence (Gottlieb, 2006), but instead recognize that ELLs are often able to communicate sophisticated understanding of mathematics using multiple representations and draw on a range of resources to support their learning, including peers, family, and experiences (Aguirre et al., 2012). ELLs should have opportunities to make use

build meaning from mathematical problems.

One way that is often recommended for helping ELLs build a connection between the natural language and mathematical symbols is to engage them with a third representation, Carey, D. A., Fennema, E., Carpenter, T. P., & Franks, M. visualizations. For example, in the problem analyzed here, a teacher may help an ELL to visualize the context by drawing five bracelets or five friends with one bracelet each. Students may also visually represent the money spent on bracelets (\$16 - \$3 = \$13) with 13 dots on paper, which they may then partition out one at a time to each of the five friends. However, because 13 is not a multiple of 5, the answer is not a whole dollar amount and students may not find the visual representation useful. In this instance, a visual image may not be sufficient for helping ELLs develop meaning for all word problems, but may help students recognize the need for symbols, demonstrating again the need for development of strong symbol sense to secure ELLs' success in working with real world situations.

The framework presented in this paper can help teachers connect the problem solving stages to the semiotic systems while providing elements of symbol sense that students, in de Oliveira, L. C. (2012). The language demands of word particular ELLs, can develop in order to work with mathematical word problems. This framework was designed and applied to word problems in middle school mathematics where students begin learning algebra. However, the framework can be adapted and used in other grade levels as well. We see this as one tool for helping teachers to think about new ways of helping ELLs work fluently within the multiple semiotic systems of mathematics in productive and meaningful ways.

Discussion And Reflection Enhancement (DARE) Post-Reading Questions

- 1. How do natural language, symbol sense, and visual representation relate to equity and excellence for ELLs?
- 2. Consider the test item in Figure 1. Would you consider this item reasonable for 7th-grade ELLs to know how to solve? Why or why not?
- 3. What does Table 1 reveal about the complexities of mathematics learning for ELLs?
- 4. How can we best prepare teachers to consider the multiple semiotic systems described in the article to address the needs of their current or future ELLs?
- 5. Use the framework described in this article to analyze the test item below (Indiana Department of Education, 2012):

Test Item

- a) Linda sells video game systems at an electronics store. She earns \$80 every week plus \$7 for every video game system that she sells. Write an expression that represents Linda's weekly earnings given the number of video game systems (v) she sells.
- b) Linda has already saved \$250. Her goal is to have a total of \$600 after working two more weeks. What is the minimum number of video game systems Linda must sell in the next two weeks in order to reach her goal?
